

## INDICATION TO DELIVER OLIVES

The circuit in the factory to deliver olives has a mandatory passage following the red line in the map displayed above. All partners must follow the indicated path leading to the stock area where the olives are transferred into number and personalized containers belonging to the oil mill. Once this has taken place, the vehicle may proceed towards the exit without interfering with weighing procedures.

The oil mill workers will weigh the containers with the help of a forklift and a scale with a maximum capacity of 1500kg. the product is then registered creating a document where raw materials must be traceable. This document indicates where the material comes from and its classification, biological or conventional. The product is then stored and processed based on a specific order.

For massive quantities of olives the weight is measured by weighing the vehicle while containing the material and once the latter has been unloaded to determine the difference in weight. This is done using a large scale with a maximum capacity of 0.2 tons. In this case a traceability document is also released.

During the processing the waste material is recycled thus avoiding any waste. Specifically the pomace (the material deriving from the pressing) is stocked in a specific area and it is slowly recovered by a local co-op that uses its potential inside a biomass plant for the production of energy.

The residual liquids are in turn deposited in specific containers where they are partially used for fertigation and partially recovered by a local biomass plant.
